JIM LEWIS GALVANIZE DSI

## TRADING STRATEGY:

MONETIZING ELEVATED EARNINGS EXPECTATIONS

#### **OVERVIEW**

Earnings releases: 4x per year

Earnings above estimates usually result in stocks outperforming

Our target is cases where companies beat consensus estimates but see their stocks fall

A strategy that could identify these situations would create significant value

#### GOAL

SYSTEMATICALLY IDENTIFY THESE SITUATIONS WELL ENOUGH TO GENERATE CONSISTENT TRADING PROFITS

## STOCK SAMPLE

#### • **SELECTION CRITERIA:**

- > \$100 MM in Sales over previous 4 quarters (total)
- ≥ \$15 MM in Average Daily Traded Value over previous 3 months

#### • TIME FRAME:

Earnings reports from 1Q14 through 3Q18

## STOCK RETURNS

#### • TIME HORIZON:

Measured price change from the day before earnings were announced (t-1) until three days after (t+3)

#### RETURN TYPE:

Converted to a market relative return by adjusting for the return of the S&P 1500 over the same period

## LABEL GENERATION

## TARGET LABELS: BASED ON TWO RULES

Announced earnings significantly<sup>†</sup>
 exceeded analyst consensus estimates

&

 Relative returns over the period of measurement were ≤ -5%

 $<sup>^{\</sup>dagger}$  Significantly here is defined by exceeding the mean estimate by >= 0.25 of the total spread in the distribution of estimates

#### **DATA SOURCES**

#### **Factset Research Systems:**

Financial data, downloaded as csv files, through customized database queries

#### Quantcha data, via Quandl:

Historical and implied volatility data from Quantcha, accessed via the Quandl platform

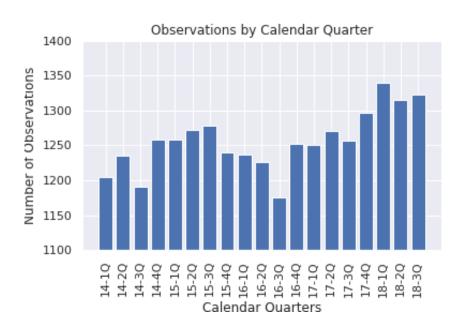

## EXPLORATORY DATA ANALYSIS

# UNDERSTANDING THE DATA SET

#### **OBSERVATIONS & TARGETS OVER TIME**

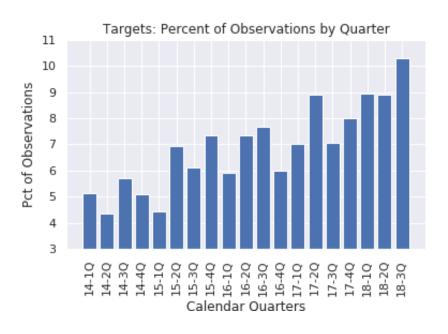

#### **Observations:**

n ≈23,900 ≈1,250 per qtr

#### **Targets:**

Avg 6.8% of obs / qtr Range from 4.4% to 10.3%

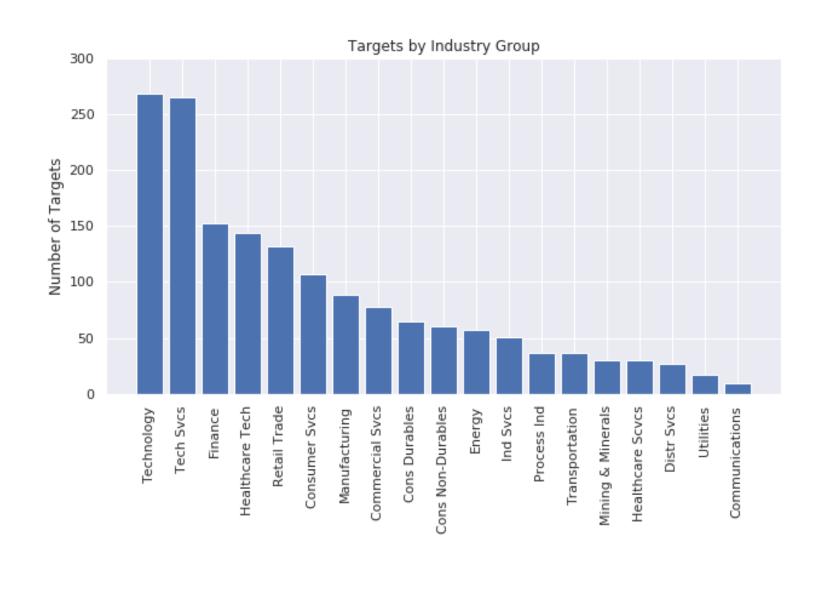

## EARNINGS EVENT RETURN DISTRIBUTION

Approximately Normally Distributed Around Zero

σ ≈ 8%

# TARGETS BY INDUSTRY GROUP

#### FEATURE TYPES & TRANSFORMATIONS

#### **FEATURE TYPES:**

- Stock valuation
- Stock performance
- Earnings estimate revisions
- Analyst ratings
- Historical company financial performance
- Stock volatility data (historical & options implied)
- Industry group classification

#### **TRANSFORMATIONS:**

- Absolute (un-transformed)
- Relative to all stocks in sample (by qtr)
- Relative to industry group peers (by qtr)

## MACHINE LEARNING

## MODEL SELECTION & TESTING METHODOLOGY

#### MODEL SELECTION

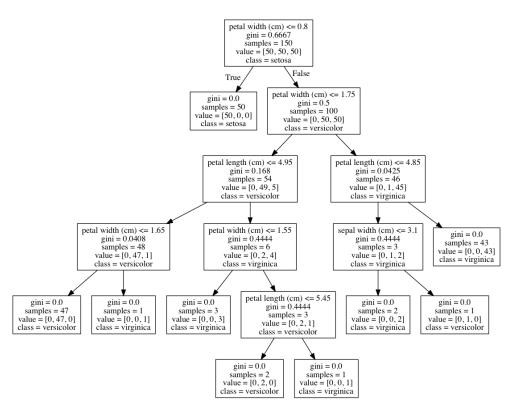

#### **KEY CONSIDERATIONS:**

- Significantly imbalanced classes
- Soft classification desired
- Mix of numerical and categorical data
- Standardization problematic due to mix of temporal spaces in data
- Significant complex interactions between features likely

#### **CONCLUSION:**

Tree-based models (Random Forest & Gradient Boosting) most appropriate

#### Example Decision Tree

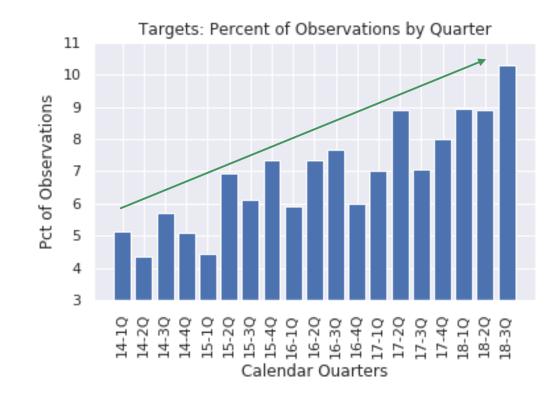

#### METHODOLOGY CHALLENGE

#### **CHALLENGE:**

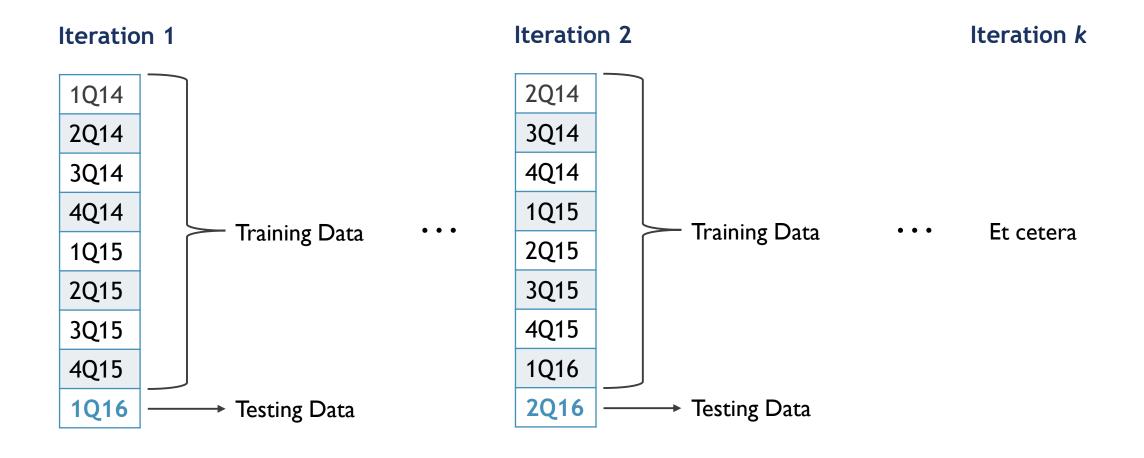

- The proportion of observations in the target class shows a rising trend over time.
- Typical random train/test splitting and crossvalidation methods showed some random instability, as a result.

#### **SOLUTION:**

 Sequential simulations based on look-back windows of both 4 and 8 quarters of data, in order to generate probability predictions for the following quarter

#### METHODOLOGY ILLUSTRATION

#### MODELING OBSERVATIONS

- Random Forest models consistently generate AUC of ROC ≈ 0.65
  - Performance is relative insensitive to tuning parameters
  - Initial tests of Gradient Boosting models performed slightly better, but tuning them proved inordinately time consuming, given the multiple simulations
- False positives are a significant issue
  - Positive Predictive Value (aka Precision) rarely exceeds 0.20 and never does so consistently
- Estimated profits based on average values for correct vs. incorrect classification often severely overestimate profitability compared to simulation using actual returns

#### **Detailed Results Example**

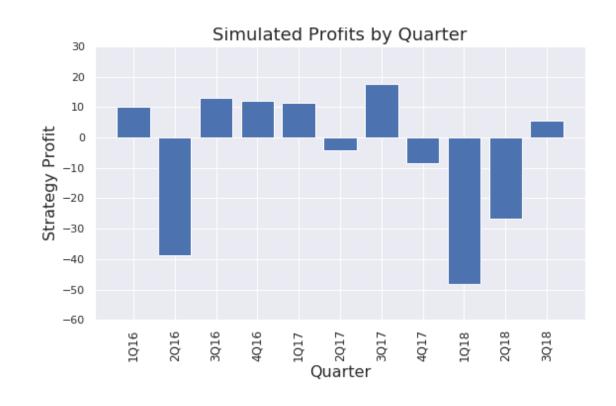

Positive Signals		Naïve		Simulated Profits		
True	False	Total	PPV	Profit Est.	8Q Model	4Q Model

## 3Q18 RESULTS –

### **SUCCESS**

#### SIMULATION OVER MULTIPLE QUARTERS TELLS ANOTHER STORY

- Results shown to the right are based on a threshold probability level of 0.10
- Simulation assumes investment of 5 units for every instance of a signal (probability of target ≥ 0.10)
- Large down quarters in 2Q16, 1Q18, and 2Q18 overwhelm the fairly consistent results seen in other quarters
- Adverse Selection: While the model does a good job identifying favorable situations for betting against stocks, it also seems to identify some of the most risky bets.

#### **NEXT STEPS**
